

CASE 1

- Male, 50 days-old
- Weight: 2,700 g (15°); length 50 cm (50°); BMI 10,88
- During the second day of life, it was noted that the patient had distended abdomen and was unable to pass meconium without rectal stimulation → **diagnosis of Hirschsprung's disease**
- For the next few days recurrent apnea and hypercarbia leading to the clinical suspicion of **Congenital Central Hypoventilation Syndrome (CCHS)**
- Baby had mutations in the PHOX2B gene (alanine repeat expansion number 20/26), confirming the diagnosis.

Congenital Central Hypoventilation Syndrome (CCHS)

- Rare life-threatening disorder of autonomic dysregulation with hypoventilation during sleep so lifelong ventilatory assistance is necessary.
- PHOX2B is the only gene in which mutation is known to cause CCHS
- The most frequently found mutation is a polyalanine expansion in exon 3. The normal genotype has a sequence of 20 alanines (20/20 genotype). CCHS occurs from four extra alanines in one of the alleles (20/24 genotype).
- There is a correlation between genotype and phenotype: the higher the number of alanines, the greater the severity of clinical findings.
- In 1978, Gabriel Haddad was the first author to describe the association between CCHS, Hirschsprung's disease (HSCR)

POLYGRAPHY STUDY

Central apnea and periodic breathing

POLYGRAPHY STUDY

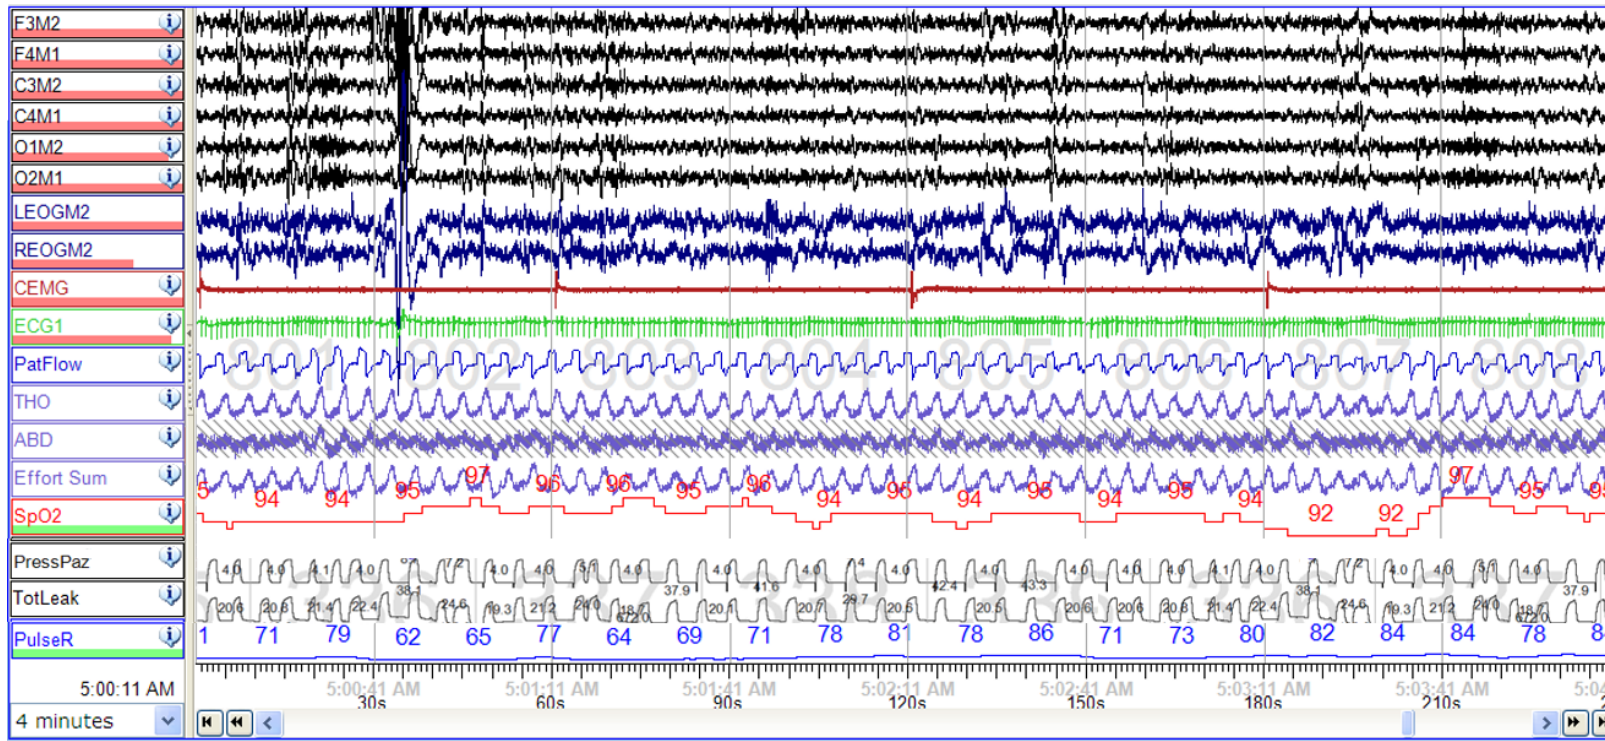

PARAMETERS	BASELINE
Mean SaO2 (%)	93
Minimal SaO2 (%)	77
SaO2 < 90% (%TST)	7
Desaturation Index (n° desat >4%/h)	31,4
AHI (n° obstructive/mixed apneas hypopneas/h)	0,9
Central Apnea Index (n° central apneas/h)	4,9
Periodic breathing (% time)	35
Mean tcCO2 (mmHg)	48
Maximal tcCO2 (mmHg)	58
Time spent tcCO2 > 50 mmHg (%TST)	56

PG in NIV

Mean SaO2 (%)	98,8
Minimal SaO2 (%)	86
SaO2 <90% (%TST)	0,1
ODI (n° desat >4%/h)	1,5
AHI (n° /h)	2
Central Apnea Index	0,8
Periodic Breathing (% time)	9
mean tcCO2 (mmHg)	44
maximal tcCO2 (mmHg)	52
Time >50 mmHg(%TST)	11

CCHS - NIV

- Technological advances allow patients with mild to moderate phenotypes to receive adequate support by non-invasive ventilation (NIV), or diaphragm pacing (or combination of the two) avoiding the need for long-term ventilation by tracheostomy
- Nasal BiPAP ventilation is a safe, well-tolerated, and noninvasive means of providing ventilatory support that is suitable in the first year of life. The equipment is simple to use, and acceptance of this mode of ventilatory support was excellent in the 9-month-old infant
- CCHS provides an unusual insight into medical decision-making around long-term ventilator support of children as the organ damage or disabilities associated with the usual situations of long-term ventilation use are stripped away.

CASE 2

- Male, 3 months-old
- Weight: 5,45 g (15°); length 65 cm (85°); BMI 12,9
- 10 days of life: diagnosis of Congenital muscular dystrophy with absent merosin (Laminin 2) on skeletal muscle biopsy, confirmed by mutation analysis.
- 2 months of life: night desaturations, intercostal retractions, poor suction and swallow

Merosin deficient congenital muscular dystrophy 1A (MDC1A)

- Results from mutations in the /react-text *LAMA2* react-text: 230 gene
- The phenotype includes elevated serum creatine kinase levels >1000 U/l, onset of severe weakness within the first six months of life and proximal joint contractures
- Patients with absent merosin staining were more likely to require ventilatory support in comparison with those who have residual staining.

POLYGRAPHY STUDY

PARAMETERS	BASELINE	NIV (7 days)
Mean SaO ₂ (%)	89	93
Minimal SaO ₂ (%)	75	0,0
SaO ₂ < 90% (%TST)	64,1	0,0

NOCTURNAL POLYGRAPHY

Severe Obstructive Sleep Apneas

WICH MODE OF VENTILATION?

PSV: IPAP of 18 cmH₂O and EPAP of 5 cmH₂O

CASE 3

- Male, 3/12 months-old
- Weight: Kg 5,380
- Length 59 cm
- CC 40 cm

- Acute dyspnea
- Stridor
- Hypercapnia
- Bronchoscopy: Tracheomalacia
- Normal bronchoalveolar lavage fluid culture, viral analysis, differential cells count and lipid-laden index

Dynamic CT scan

Expiratory deformation of the main airways with a significant caliber reduction of the main left bronchus (3.5x2 mm), carina and upper lobar right bronchus consistent with a Tracheobroncomalacia diagnosis.

Baseline Psg + CO₂+ ABG

Parameters	Values
pH	7,39
PaCO ₂ (mmHg)	58,1
PaO ₂ (mmHg)	101,2
HCO ₃ ⁻ (mmol/L)	35
BE (mmol/L)	10,2

Diurnal hypercapnia

Severe Obstructive Sleep Apneas

Nocturnal hypoventilation

Parameters	Values
TST (hh.min)	06.42
Mean SaO ₂ (%)	99,6
Minimal SaO ₂ (%)	80
SaO ₂ < 90% (%TST)	0,2
Desaturation Index (n° desat >4%/h)	8,7
AHI (n° obstructive/mixed apneas hypopneas/h)	19
Central Apnea Index (n° central apneas/h)	2,1
Mean tcCO ₂ (mmHg)	61
Maximal tcCO ₂ (mmHg)	66
Time spent tcCO ₂ > 50 mmHg (%TST)	97,3

Tracheobroncomalacia

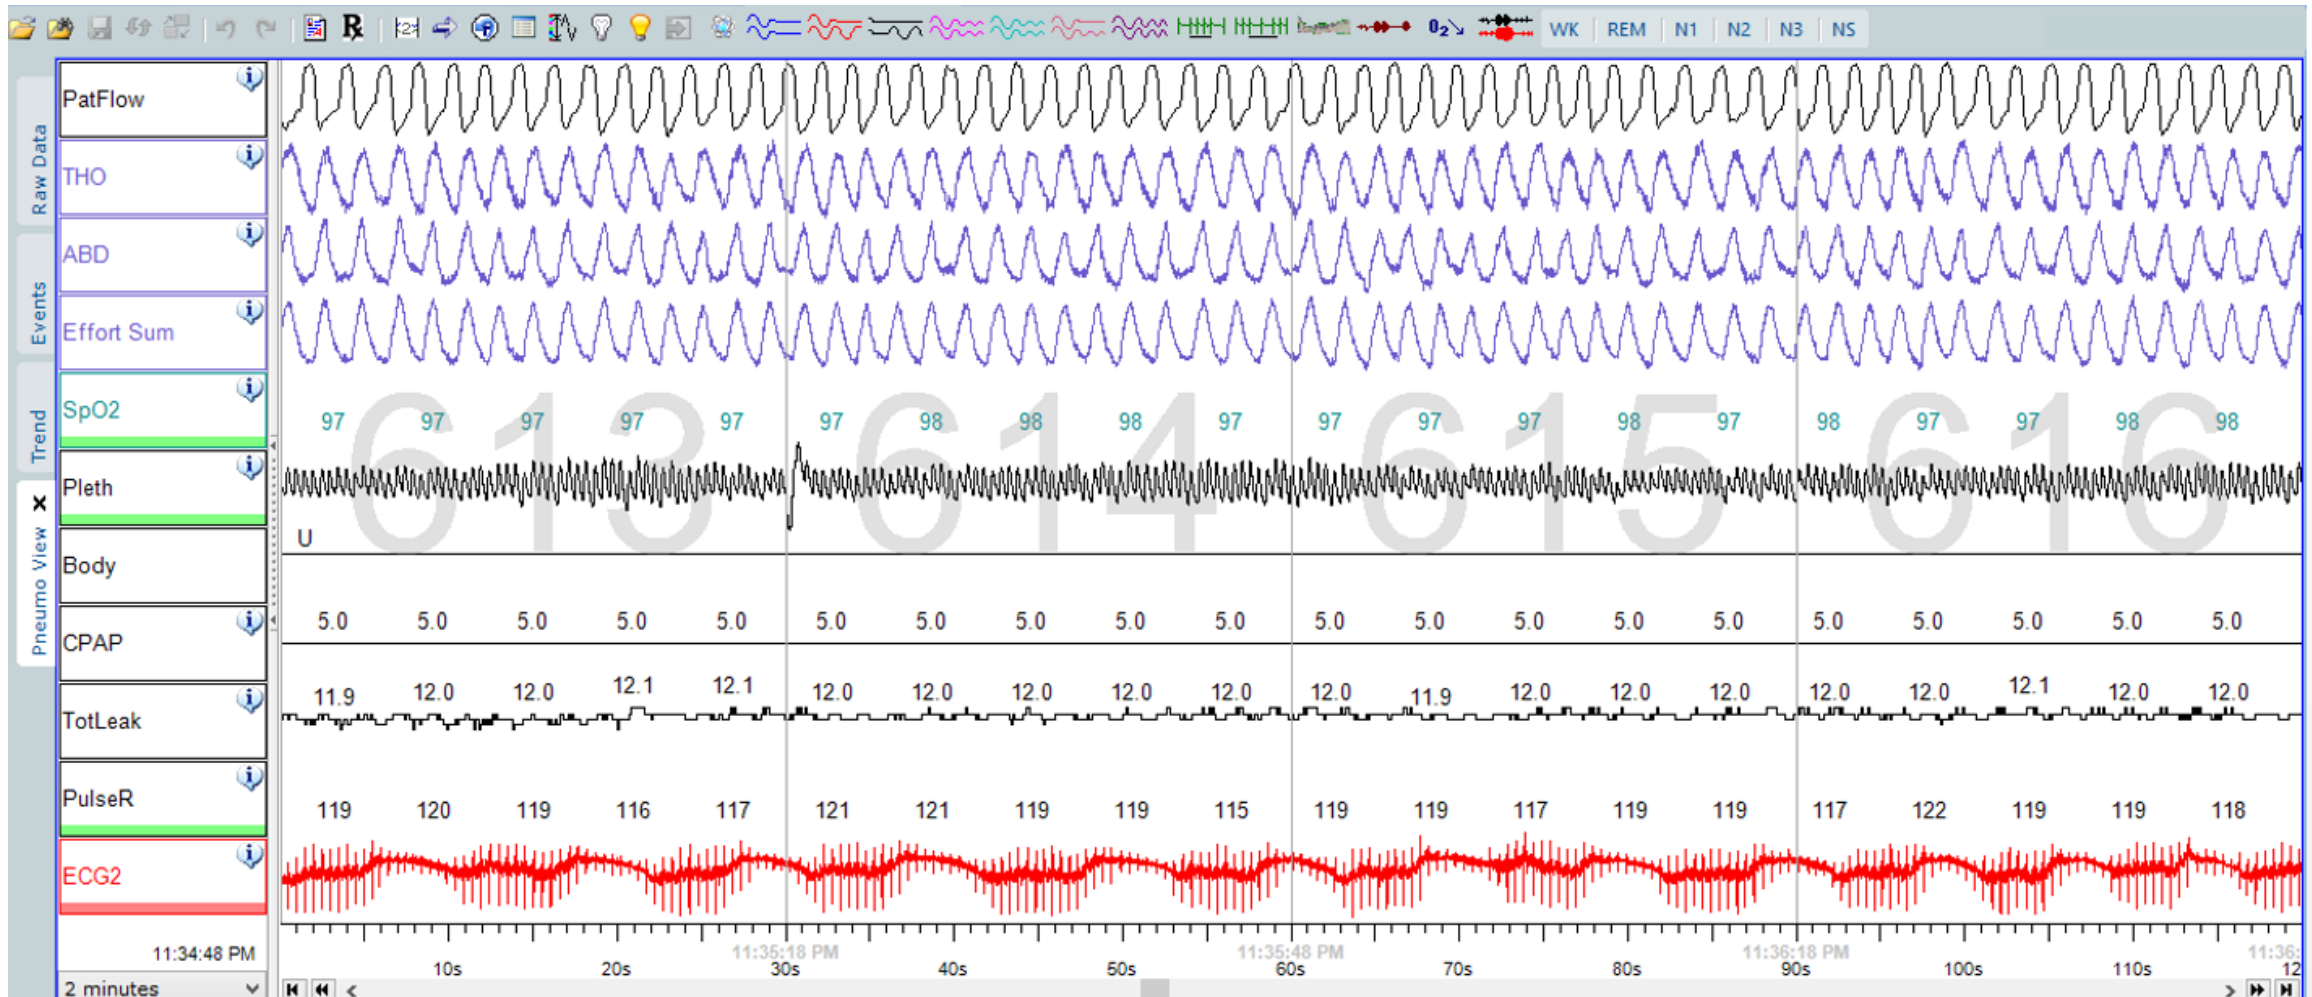

- Tracheomalacia (TM) refers to diffuse or segmental tracheal weakness.
- Tracheobronchomalacia (TBM) exists when the weakness extends into one or both main stem bronchi.
- Both conditions result in exaggerated luminal narrowing during expiration and widening during inspiration
- CPAP can be use as a bridge-treatment waiting for an increased rigidity of the bronchial cartilage with growth
- CPAP delivers a continuous distending pressure throughout the respiratory cycle that reduce the work of breathing
- Surgical therapy is preferred in very severe cases

HELMET-CPAP → Nasal-cpap

- He started a trial of non-invasive respiratory support with Helmet-CPAP (5 cmH₂O)
- After 2 weeks training period, good compliance with nasal-CPAP (5 cmH₂O)
- Improvement of dyspnea and stridor
- Further reduction of tcpCO₂ and of obstructive sleep apneas

Psg in CPAP 5 cmH₂O

Psg+CO₂+ ABG

Parameters	Helmet-CPAP (2 days)	Nasal-CPAP (15 days)
pH	7,37	7,43

CASE 4

- Male, 3/12 months-old
 - Weight: Kg 4,820
 - Length 57 cm
 - CC 39 cm
-
- Inspiratory stridor since second day of life
 - Intercostal retractions
 - Failure-to-thrive
 - No neonatal or perinatal issues

SpO₂/CO₂ sleep STUDY

Parameters	Values
TST (hh:min)	9.31
Mean tcCO ₂ (mmHg)	45,7
Maximal tcCO ₂ (mmHg)	52,1
Time spent tcCO ₂ > 50 mmHg (%TST)	1
Mean SaO ₂ (%)	97,7
Minimal SaO ₂ (%)	87
SaO ₂ < 90% (%TST)	0,1
Desaturation Index (n° desat >4%/h)	6,6

Lung function tests

- Inspiratory obstruction
- V_t 2,7 mL/kg
- RR 85 b/min
- PTIF 80mL/s
- PTEF 57 mL/s
- TPTEF/Te 0.43
- TEF50/TIF50 0.8

CPAP 6 cm H₂O

- Weight gain
- Good adherence
- No stridor or intercostal retractions

Laryngomalacia

- Laryngomalacia refers to collapse of the supraglottic structures during inspiration
- Laryngomalacia manifests with inspiratory stridor, usually in the neonatal period.
- The diagnosis of laryngomalacia is usually suspected based upon the history and physical examination. It is confirmed with flexible fiberoptic laryngoscopy
- CPAP or BIPAP may be indicated in infants with comorbidities, failure to respond to surgery or as a bridge to surgical intervention
- Infants with moderate or severe laryngomalacia (stridor with feeding difficulty, dyspnea, tachypnea, cyanosis, apnea) should be referred to an otolaryngologist for full endoscopic evaluation and intervention

EPIGLOTTOPLASTY

Case 5

- 10 month old boy with recurrent cyanotic spells after crying.
- After first episode: chronic cough and noisy breathing. Discrete stridor. Recurrent vomiting.
- Investigations previously performed in another hospital:
 - Chest X-ray
 - pH-study
 - Cardiac ultrasound
 - Sleep study
 - All were normal.

Case 5

- Bronchoscopy:
 - Distal tracheomalacia.
 - Trapping of secretions
- Additional investigations:
 - PSG: oAHI = 11. Suggestive for GERD.
 - CT: no vascular compression

Case 5

- Treatment:
 - Omeprazole
 - Respiratory physiotherapy and mucolytics by nebuliser
- Recurrent respiratory infections:
 - No effect chronic antibiotics
 - Parents requested surgery
 - CPAP trial with positive effect – CPAP 5 cm H₂O normalized sleep study

Case 5

- After a few weeks, patient did not tolerate the nasal mask.
 - Management?
 - Switched to Optiflow interface on regular CPAP device.

OPTIFLOW JUNIOR

The Optiflow™ interface for chronic CPAP use in children

C. Overbergh¹; S. Installe¹; A. Boudewyns, MD, PhD²;

K. Van Hoorenbeeck, MD, PhD^{1,3}; S.L. Verhulst, MD, PhD^{1,3}

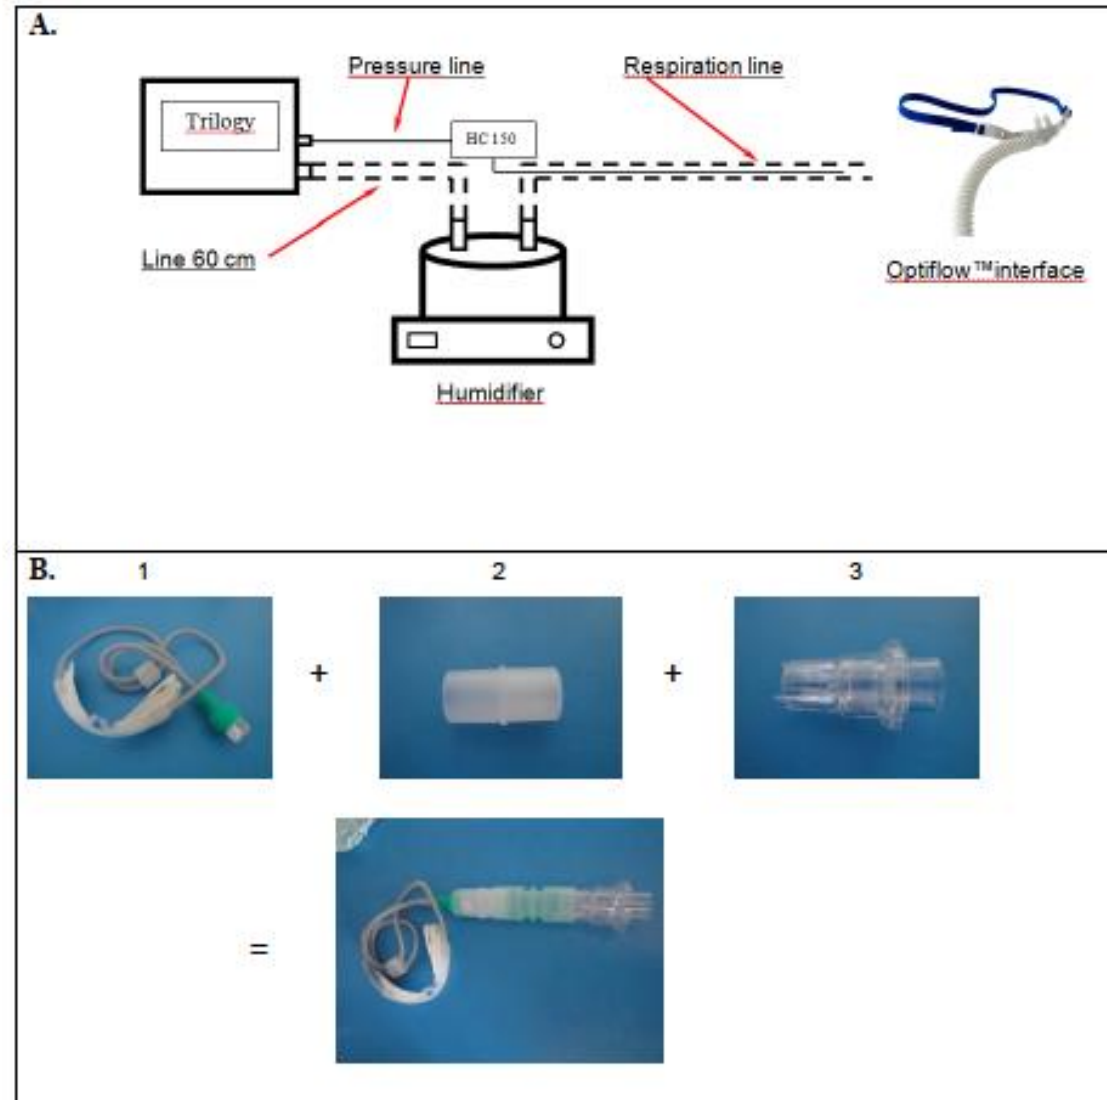

Table 1: Description of patients on chronic NIPVV with Optiflow™ interface

Patient Description	Effective CPAP pressure	Obstructive AHI _{baseline} (n/hr)	Obstructive AHI _{CPAP} (n/hr)
7 month old girl with persistent tracheomalacia after correction of a double aortic arch	5 cm H ₂ O	20	3.2
2 year old boy with OSAS and tracheobronchomalacia	7 cm H ₂ O	5.8	3.2
4 year old boy with severe OSAS and partial trisomy 9	6 cm H ₂ O	99.3	7
5 year old boy with REM-sleep related OSAS and a chromosome Xp27.3-q28 duplication	8 cm H ₂ O	99.7	6.5
5 year old boy with OSAS and Down syndrome	4 cm H ₂ O	6.5	0
9 year old boy with OSAS and Down syndrome	6 cm H ₂ O	70	22
15 year old boy with OSAS and cerebral palsy	6 cm H ₂ O	16.6	4
5 year old girl with OSAS due to tracheomalacia	5 cm H ₂ O	20	3.2
4 year old boy with OSAS due to pharyngolaryngomalacia	7 cm H ₂ O	40.5	6

Case 5

- Practical aspects of the Optiflow interface on a regular CPAP device:
 - Leak is very low: disconnect low leak alarm
 - Whisper swivel to allow leaks
 - Use other alarms
 - Use of a battery
 - The size of the cannula was based on the manufacturer's recommendation
 - Excellent compliance
 - Not suitable for bilevel ventilation

Case 6

- Full-term infant
- Referral because of obstructive breathing pattern and dysmorphic features
- Sleep study

Case 6

No. of respiration events:	554	RDI:	64,7 /h
No. of apnea (TST):	203	OAHI	46,1 /h
Central:	159	Central Apnea Index	18,6 /h

Case 6

Case 6

- Management?
 - DISE: oropharyngeal hypotonia
 - CPAP or NIV?

Case 6: CPAP 5 cm H2O

Aantal events:	41		
Aantal apnoes:	36	Centrale apnoe index:	4,6 /h
Centrale:	36	Obstructieve apnoe index:	0,0 /h
Obstructieve:	0	AHI:	5,2 /h
Mixed:	0	OAHl (OA+MA+OH):	0,6 /h
Aantal hypopnoes:	5	Hypopnoe index:	0,6 /h
Centrale:	0		
Obstructieve:	5		
Non classified:	0		
Totale duur apnoes:	3,6 min	Totale duur hypopnoes:	0,6 min
Langste apnoe:	10,2 s	Langste hypopnoe:	9,8 s

Case 6

- Mixed sleep apnea:
 - Predominant obstructive abnormality: CPAP will improve both obstructive and central component. Central apneas are a consequence of an irregular breathing pattern.
 - Predominant central abnormality: obstructive events will change into more central events. This is an indication for further investigations and NIV.

Case 7

- Boy, 1.5 years
- CP after peripartal asphyxia – severe neurodevelopmental delay

- Generalized hypotonia
- Recurrent vomiting
- Chronic cough and stridor
- Failure to thrive
- Chronic aspiration:
 - No mouth feeding.
 - Aspiration of saliva.

Case 7

- Sleep study: continuous snoring and paradoxical breathing with low saturations.
- CT thorax: normal
- Laryngoscopy: hypertrophic adenoids and laryngomalacia.
- Barium swallow:
 - Aspiration
 - Important reflux

Case 7

- Nissen surgery
- Adenoidectomy with repeated and severe desaturations in the days following surgery.
- Repeat study: residual obstructive breathing pattern with paradoxical breathing, oAHI = 6.

- Management?
- Ethical concerns?

Case 7

- Nissen surgery
- Adenoidectomy with repeated and severe desaturations in the days following surgery.
- Repeat study: residual obstructive breathing pattern with paradoxical breathing, oAHI = 6.

- CPAP 8: normal breathing pattern, well tolerated.
- Immediate effect on upper airway secretions as well as on stridor while awake (much less pronounced)

- Patient received tonsillectomy at the age of 6 years and CPAP therapy was stopped afterwards.
